🐝 Pollinators: Nature's Delivery Service 🌸

Life Science — Plants & Ecosystems — Unit 1, Lesson 2 of 6

📚 **Grade:** 2nd Grade ⏱️ **Duration:** 45 minutes 🔬 **Subject:** Life Science — Plants & Ecosystems 🧰 **Kit Lesson:** No

Without pollinators, most of the fruits and vegetables we eat wouldn't exist!

📋 **NGSS Standard:**
2-LS2-2 — Develop a simple model that mimics the function of an animal in dispersing seeds or pollinating plants.

🎯 Learning Objective

Students will *explain* the role of pollinators in plant reproduction and *create* a model demonstrating how pollen transfers from flower to flower.

🔬 The Big Idea

Flowers need pollen moved from one flower to another to make seeds. **Bees, butterflies, birds, and even wind** do this job — they're called **pollinators**, and without them, most fruits and vegetables wouldn't exist.

💡 **Key vocabulary:** pollinator, pollen, nectar, anther, stigma, sepal, petal, seed

🌿 The Science

Flowers are actually *advertisements* — their bright colors and sweet smells are designed to attract pollinators. When a bee lands on a flower to drink nectar, it accidentally picks up tiny **pollen** grains on its fuzzy body. When it visits the next flower, some of that pollen rubs off onto the flower's **stigma** — the sticky tip in the center. This is **pollination**! Once a flower is pollinated, it can grow seeds, and those seeds can grow into new plants.

Different pollinators match different flowers — it's like a lock and key system evolved over millions of years. Hummingbirds have long beaks for tubular flowers. Bumblebees need wide, open flowers they can land on. Moths visit white flowers that bloom at night. Wind-pollinated plants like grasses don't need to attract anyone — they just make enormous amounts of lightweight pollen and let the breeze do the work.

📦 Materials

🏠 For the "Be a Bee!" Activity

- 4 paper cups (your model "flowers")
- Yellow cornmeal, flour, or powdered spice (your "pollen") — about 1 tablespoon per cup
- Cotton balls or fuzzy pipe cleaners (your "bee" — the pollinator)
- Colored paper to decorate flower cups (optional)
- A tray or sheet of newspaper to catch spills

🌸 For the Flower Anatomy Mini-Lab

- 1 real flower per child or pair if possible (lilies, daisies, tulips, or grocery-store flowers work well)
- The printable Flower Anatomy & Pollination Reference Card
- Magnifying glass (optional)
- Dark paper or tray to catch loose pollen (optional)

🧰 For the Worksheet

- Crayons or colored pencils
- Pencil for writing labels

🔬 Activity 1: Be a Bee!

Step 1 — Set Up Your Flowers (5 min)
Place 4 paper cups on a tray. Put a small amount of yellow cornmeal or flour in the center of each cup. These are your model flowers — the yellow powder is the pollen! If you like, decorate the outside of the cups with colored paper petals.

Step 2 — Meet the Bee (2 min)
Give each student a cotton ball or fuzzy pipe cleaner pom. Say: *"This is your bee! Look at how fuzzy it is. Why do you think real bees are fuzzy?"* Let them guess. (The fuzz — plus static electricity — catches and holds pollen grains!)

Step 3 — Visit Flower 1 (3 min)
Press your cotton ball / pipe cleaner gently into the center of Flower 1. Watch the yellow "pollen" stick to the fuzz! Lift it up — you should see pollen clinging to it. Ask: *"What happened? Where did the pollen go?"*

Step 4 — Visit Flower 2 (3 min)
Now press the same pollen-covered cotton ball into Flower 2. Watch the pollen transfer! Some will fall off onto the flower. Say: *"That's pollination! The bee just delivered pollen from flower to flower."*

Step 5 — Repeat & Observe (5 min)
Try visiting all four flowers in different orders. Which flower has the most pollen after several visits? Why? Compare a cotton ball vs. a pipe cleaner — which picks up more pollen? (The pipe cleaner! That's why bee fuzziness matters.)

Step 6 — Debrief Discussion (5 min)
Ask the discussion questions below. Connect the model to real life: the cotton ball = bee, the yellow powder = real pollen, the cups = real flowers.

🌸 Activity 2: Flower Anatomy Mini-Lab

Before students label flower parts on the worksheet, let them inspect a real flower or the printable reference card so the vocabulary has something concrete to stick to.

Step 1 — Meet the Flower Parts (3 min)
Hand out a real flower if you have one, or open the Flower Anatomy & Pollination Reference Card. Point out the **petals**, the small outer **sepals**, the powdery **anther**, and the sticky **stigma** in the center.

Step 2 — Try a Gentle Dissection (5 min)
Gently pull one flower apart together. Ask: *"Which part is making the pollen? Which part is catching it?"* If pollen is visible, tap the anther lightly over dark paper so children can see the tiny grains.

Step 3 — Connect Anatomy to Pollination (3 min)
Explain the path clearly: **pollen starts on the anther**, a pollinator brushes against it, and then some pollen lands on the **stigma** of the next flower. Tell students this is why they will use those part names on the worksheet.

📄 **Family support:** Print or open the Flower Anatomy & Pollination Reference Card during the mini-lab and worksheet time so students can keep checking the parts as they work.

🌼 Activity 3: Who Pollinates What?

Now that students have seen where pollen starts and where it needs to land, explore how different pollinators are built to move that pollen between flowers.

Hummingbird
→ Red tubular flowers 🌺
Long beak fits perfectly inside the tube to reach nectar

🐝

Bumblebee
→ Open, wide flowers 🌻
Big enough to land on — a bee-sized landing pad

Moth

→ White flowers (night blooming) 🌕

Moths are nocturnal — white flowers glow in moonlight

💨

Wind

→ Grasses & trees 🌾

No color, no smell needed — just clouds of tiny, light pollen

💬 Discussion Questions

🗣️ **Question 1:** "Why do you think flowers are bright colors and have sweet smells? What would happen to a flower that had no color or smell?"

Suggested answer: Flowers are bright and fragrant to attract pollinators — bees and butterflies find them visually and by scent. A flower with no color or smell would attract fewer pollinators, meaning less pollen transfer, fewer seeds, and fewer new plants. Some wind-pollinated plants (like grass) actually DON'T have showy flowers — they don't need to attract anyone!

🗣️ **Question 2:** "If all the bees disappeared, what do you think would happen to our food supply?"

Suggested answer: It would be a catastrophe! About 1/3 of the food humans eat depends on bee pollination — fruits, vegetables, nuts. Without bees, many crops would fail or produce very little. This is why declining bee populations (due to pesticides and habitat loss) is such a serious environmental concern.

🚀 Extensions

- 🌸 **Repeat the Mini-Lab with Another Flower:** Compare two different flowers and see whether both have easy-to-find petals, sepals, anthers, and stigmas.
- 🌱 **Pollinator Garden:** Look up which local flowers attract bees in your region. Plant a pollinator-friendly garden — even one pot on a windowsill counts!
- 📚 **Read Aloud:** *"The Honeybee"* by Kirsten Hall or *"Are You a Bee?"* by Judy Allen & Tudor Humphries
- 🎬 **Nature Watch:** If it's warm outside, sit quietly near a flowering plant and count how many different pollinators you see in 5 minutes.
- 🔎 **Bee Colony Collapse:** Bee populations are declining — this is called Colony Collapse Disorder. Research what causes it and what people can do to help.

👩‍🏫 Parent/Teacher Notes

- **Teach the flower parts before the worksheet:** Use the new mini-lab and the printable Flower Anatomy & Pollination Reference Card first, then move into the worksheet while the parts are still fresh.
- **For Worksheet Part 1:** Say the path out loud as students work — *anther → bee → stigma*. That simple chant makes the arrows much easier for second graders.
- **Yellow cornmeal is ideal pollen** — it's visible, doesn't fly around, cleans up easily, and sticks satisfyingly to fuzzy things. Flour works but is messier. Powdered turmeric adds a pop of color!
- **Real flowers at home:** If you have flowers, help students find petals on the outside, sepals underneath, anthers with visible pollen, and the stigma in the center. A lily or daisy usually makes this easiest.
- **Fuzzy pipe cleaner vs. cotton ball:** The pipe cleaner picks up noticeably more "pollen" — lean into this as a teaching moment. Why are bees fuzzy? (Tiny hairs + static electricity trap pollen grains.)
- **Keep the anatomy language simple:** For Grade 2, students do not need every flower-part term. Focus on *anther makes pollen* and *stigma catches pollen*, with sepal and petal as supporting parts they can spot.
- **Real-world urgency:** Bee colony collapse disorder is a genuine and serious environmental problem. This is an excellent entry point for conservation discussions with 2nd graders — they're old enough to understand cause and effect.
- **Extension tip:** Look up your local Cooperative Extension office or a site like the Xerces Society for region-specific lists of bee-friendly plants.
- **Vocabulary to reinforce:** pollinator, pollen, nectar, anther, stigma, sepal, petal, seed

🐝 Student Worksheet: Be a Bee!

Name: _____ Date: _____

Part 1 — Show the Path of Pollen

Use the word bank and your Flower Anatomy Reference Card if you need help. Write **anther** on Flower 1, write **stigma** on Flower 2, then draw arrows to show how the bee carries **pollen** from one flower to the next.

Flower 1

Pollen starts here

_____

Write: anther

Bee / pollinator

Draw arrows to and from the bee

Flower 2

Pollen lands here

_____

Write: stigma

Your job: Draw arrow 1 from the **anther** to the **bee**. Draw arrow 2 from the **bee** to the **stigma**. Label the yellow dust as **pollen**.

📚 **Word Bank:** anther • pollen • stigma

Part 2 — Label the Flower Parts

Draw a line from each label to the correct flower part. Use the descriptions to help you!

- **Anther** _____ the part that holds and releases pollen
- **Pollen** _____ tiny grains that bees carry from flower to flower
- **Stigma** _____ the sticky tip in the center that catches pollen

Part 3 — Who Pollinates What? Match It!

Draw a line connecting each pollinator to the flower it works with. Use what you learned!

🦟 Hummingbird	draw a line →	🌾 Grasses & trees (no color, no smell)
🐝 Bumblebee	draw a line →	🌺 Red tubular flowers
🦋 Moth	draw a line →	🌻 Wide open flowers (landing pad)
💨 Wind	draw a line →	🌕 White flowers (blooms at night)

Part 4 — My Thinking 🧠

Answer in your own words:

Why is it helpful for a bee to be fuzzy?

If there were no pollinators, what do you think would happen to flowers and food?

🎨 **Bonus: In the box below, draw a bee visiting a flower and label the pollen it's carrying!**

🔑 PARENT/TEACHER ANSWER KEY — Detach before giving worksheet to students

Part 1 — Show the Path of Pollen

- **Flower 1 label:** *Anther* — this is where pollen starts.
- **Flower 2 label:** *Stigma* — this is where pollen needs to land.
- **Label near the yellow dust / path:** *Pollen*
- **Arrows:** Students should draw one arrow from the anther to the bee/pollinator and a second arrow from the bee/pollinator to the stigma.
- Accept any clear version of *anther → bee → stigma* that shows the pollinator carrying pollen between flowers.

Part 2 — Flower Parts

- **Anther** → the stalk-like structure inside the flower covered in yellow dust/powder; the pollen producer
- **Pollen** → the tiny yellow grains — in the model, this was the cornmeal
- **Stigma** → the sticky central tip of the flower; pollen must land here for pollination to occur
- *Note for real flower examination:* stamens = anther + filament (stalk); pistil = stigma + style + ovary. For 2nd grade, anther and stigma are sufficient.

Part 3 — Who Pollinates What? (Correct Matches)

Hummingbird → 🌺 **Red tubular flowers** — long beak fits the tube perfectly to reach nectar deep inside

🐝 **Bumblebee** → 🌻 **Wide open flowers (landing pad)** — bees need a flat surface to land and collect pollen

Moth → 🌕 **White flowers (blooms at night)** — moths are nocturnal; white flowers are visible in moonlight

💨 **Wind** → 🌾 **Grasses & trees (no color, no smell)** — wind doesn't need to be attracted; plants produce enormous quantities of tiny, light pollen

Part 4 — My Thinking (Model Answers)

Why is it helpful for a bee to be fuzzy?

> *The fuzz (tiny branched hairs) physically traps pollen grains as the bee brushes against flower parts. Static electricity — built up as bees fly — also attracts pollen to the hairs electrostatically. Bees even have special pollen "baskets" (corbiculae) on their hind legs to carry extra pollen back to the hive. The more surface area, the more pollen clings.*

If there were no pollinators, what would happen to flowers and food?

> *Most flowering plants would not be able to reproduce — they couldn't make seeds. Many fruit and vegetable crops (apples, strawberries, almonds, blueberries, cucumbers, etc.) would fail or produce little to no food. About 1/3 of the human food supply depends on animal pollinators, especially bees. Wind-pollinated crops (wheat, corn, rice, oats) would survive, but biodiversity and the ecosystem would suffer enormously.*

✅ What Success Looks Like

- Child can explain in their own words what a pollinator does (moves pollen from flower to flower).
- Child can correctly match at least 3 of 4 pollinators to their flower type.
- Child can identify at least 2 of 3 flower parts (anther, pollen, stigma).
- Child understands that pollinators are essential for plants to make seeds — and therefore for our food supply.

🔬 Activity Debrief Notes

- **Fuzzy pipe cleaner vs. cotton ball:** The pipe cleaner picks up significantly more "pollen." This is the model for why bees' branched hairs are so effective.
- **Cornmeal tip:** If pollen isn't sticking, try slightly dampening the cotton ball — real bees groom pollen and use a bit of nectar/saliva to pack it.
- **Multiple flower visits:** As students visit more "flowers," they'll see pollen spreading throughout all cups — great visual for how a single bee visit affects an entire field.
- **Conservation connection:** If bees fascinate your student, look up the Xerces Society or ask at a local garden center about planting bee-friendly natives in your region.
